

Alma 9 Validation

Dark Photon Samples

January 27, 2025

Pawan Johnson

Prof. Carl Gwilliam

Dr. Monika Weilers

Prof. Monica D'Onofrio

University of Liverpool

Introduction

- Validate ALMA9 version of Calypso for the track variables
- Sinead already looked at single muon samples
- Ansh looked at the A' analysis cutflow
- We want to look at the “two track reconstruction” as a function of separation between them

Data Description

- We will look at Dark-Photon decays to electron pairs
- Data samples used are
/eos/experiment/faser/data0/sim/mc24/foresee/1100{33,38,51}/
 - 110033 : Mass = 10 MeV, epsilon = 1E-5
 - 110038 : Mass = 100 MeV, epsilon = 1E-5
 - 110051 : Mass = 10 MeV, epsilon = 1E-4
- ALMA 9 samples : ./phy/s0008-dev/
- CENTOS 7 samples: ./phy/s0008-r0019/
- Chaining them together for better statistics [total 60k events]
- Can separate based on mass/couplings if interested

Overview of Validation

Objective: To Quantify two track reconstruction efficiency as a function of separation between the tracks

- Quantify separation between tracks
- Compare generic track reconstruction as a function of above
- Define an “Efficiency” and compare
- Residues?

Distribution of Track Parameters

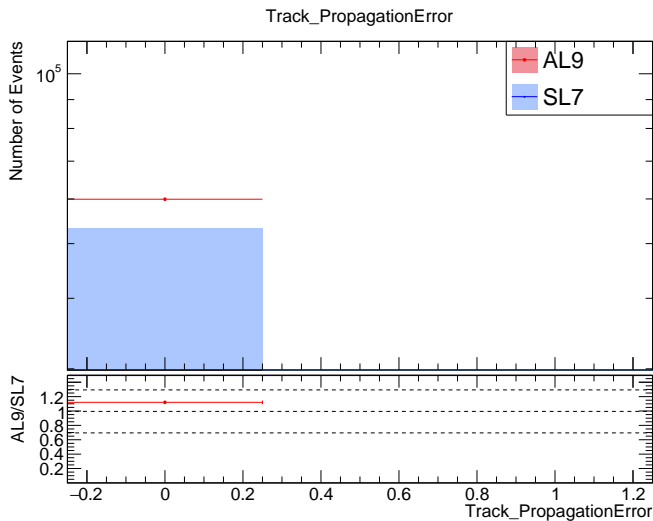

- longTracks
- Track Propagation Error
- Track Chi2
- Track Chi2perDoF
- Track nDoF
- Track charge
- Track nLayers

Distribution of longTracks

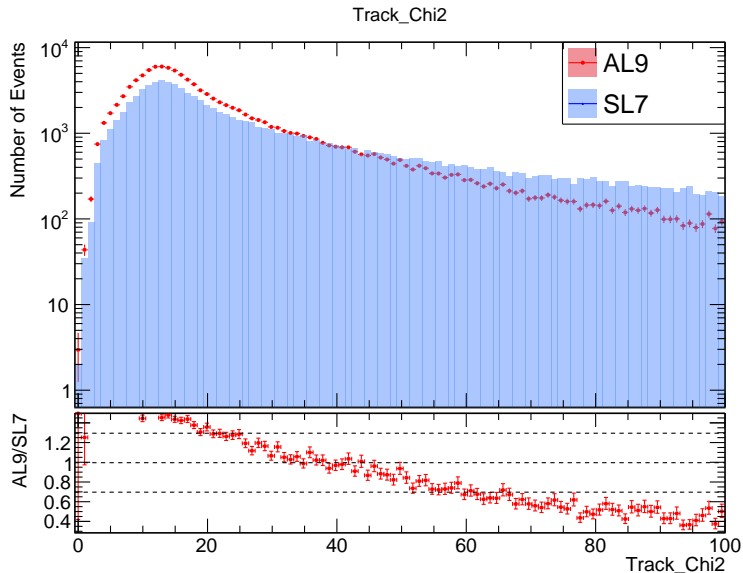

- Overall agreement is good in early bins
- Bin 0 has a drop in AL9
- longTracks 5 shows more discrepancy, Concerning?

Distribution of TrackPropagationError [SKIP]

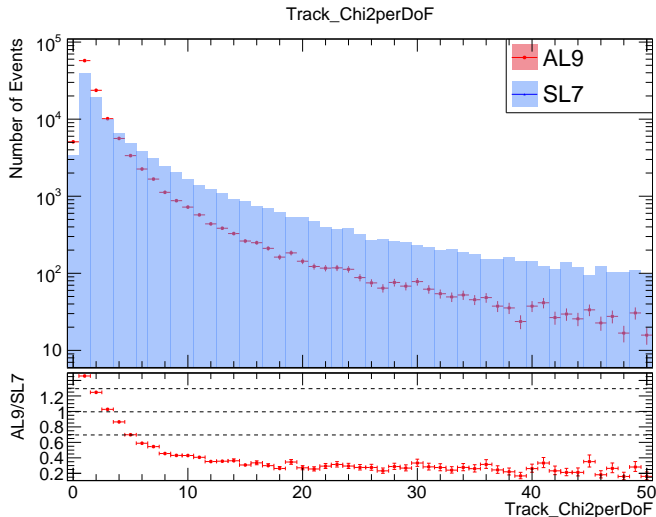

- More TrackPropagationErrors in CENTOS7.

Distribution of TrackChi2

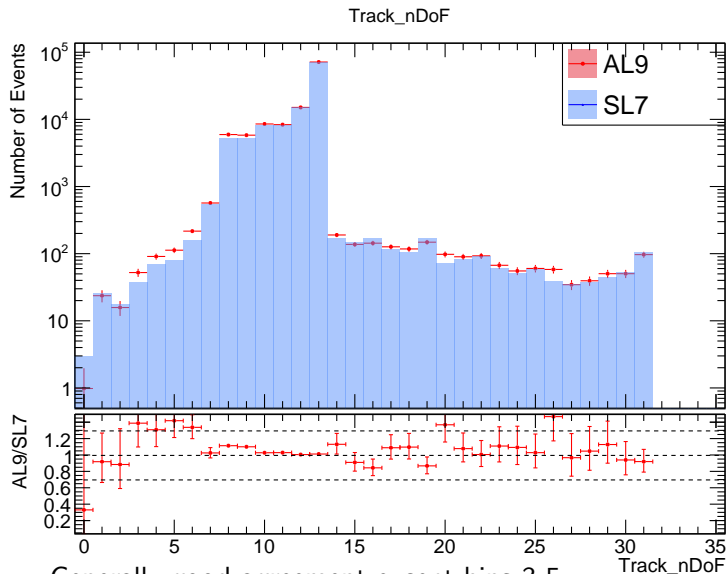

Distribution of TrackChi2perDoF

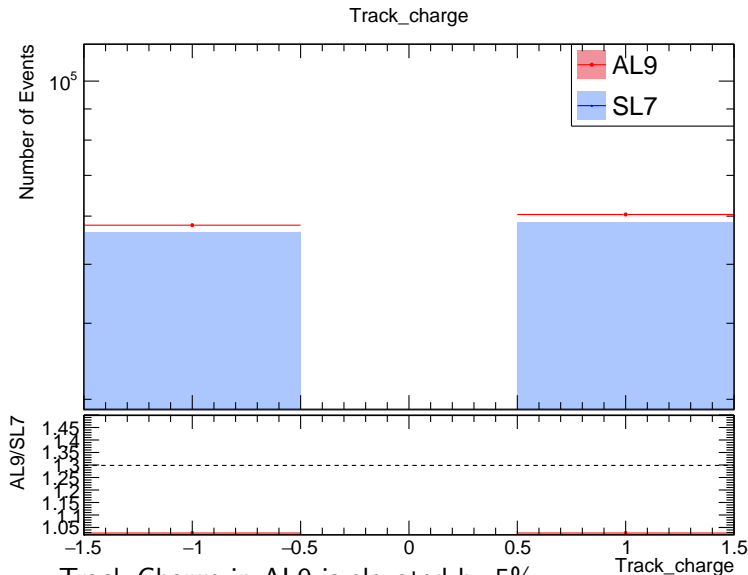

- Shows “most” improvement in ALMA9.
- More events with lower Chi2/DoF and tail is also lower.

Distribution of TrackNDoF

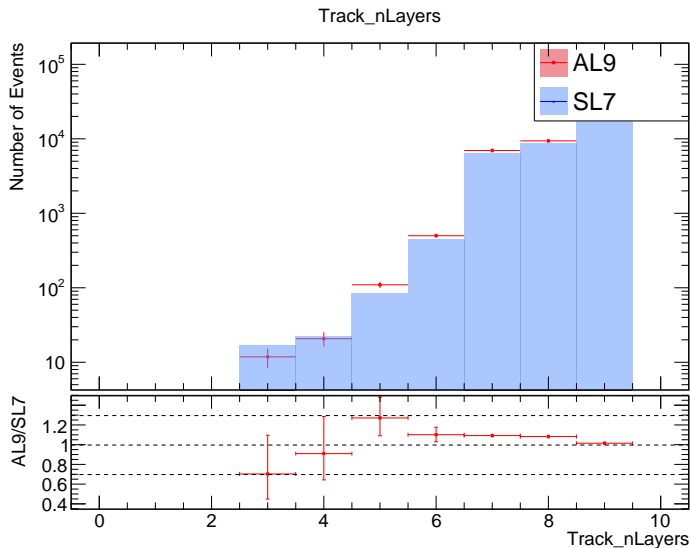

- Generally good agreement except bins 3-5

Distribution of Track Charge

- Track Charge in AL9 is elevated by 5%

Distribution of Track nLayers

- Overall we hit more layers in AL9

Quantifying Separation

Possible Track Separation Variables

- ΔR_0 : Separation between the electron and positron at the first tracking station in the x-y plane
- ΔX_0 : Same as above but only in x direction
- ΔY_0 : Same as above but only in y direction
- θ_0 : Angle between the line connection decay vertex to the two tracks at the first tracking station
- $\Delta R_P = \sqrt{\Delta\eta^2 + \Delta\phi^2}$: Momentum space separation between electron and positron

Position Based Separation variables

Figure: Tracking Station 1

ADD CODE SNIPPET

Track Separation in terms of Angle

Figure: Angle between Tracks

ADD CODE SNIPPET

Track Separation in $\eta - \phi$ Space

Figure: Angle between Momenta

TODO: Fix listing here

Distribution of DeltaR0

Distribution of DeltaR0 [Truth Level]

Distribution of DeltaX0

Distribution of DeltaX0 [Truth Level]

Distribution of DeltaY0

Distribution of DeltaY0 [Truth Level]

Comments on Position Based Separation

- Particle predominantly separated in the y-direction
 - Comes from the magnetic field's deflection
 - Positron deflected upwards, electron downwards leading asymmetry in ΔY_0 plot
 - ΔX_0 looks symmetric
 - ΔY_0 can be approximated to ΔR_0
- In general Nevents fall off as separation increases [characteristic of DP Decay?]
- Similar features seen in overlay plot but different in scale
- We can just look at the distributions using ΔR_0 as our primary variable for position based separation.

Overlay Plot

Figure: Overlay plot from Search for dark photons with the FASER detector at the LHC

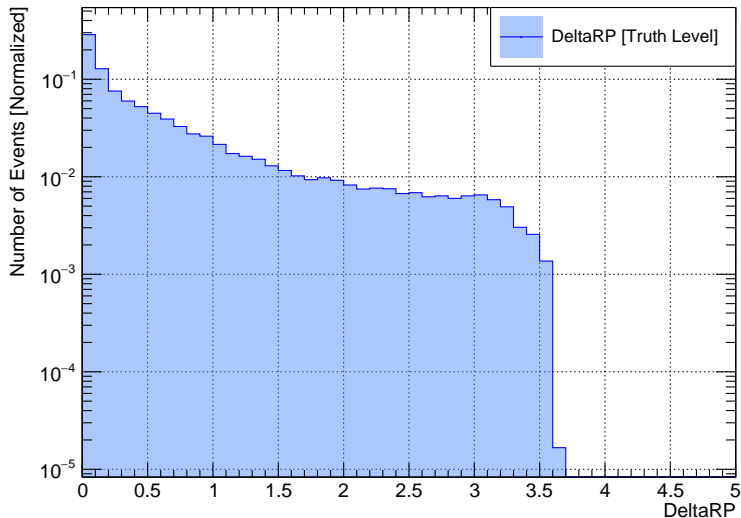

Distribution of Theta0

Distribution of Theta0 [Truth Level]

Distribution of DeltaRP

Distribution of DeltaRP [Truth Level]

Comments on Angle Based Separation

- Theta0 is a variable to separate the tracks but falls off reapidly
- DeltaRP shows a relatively flat distribution
- To calculate the separation variables the MC level information is used
 - Same across AL9 and CENTOS7
 - More robust
 - No uncertainty from the tracking itself

Events grouped by longTracks vs DeltaR0

NEvents Grouped by Track Count

Events grouped by longTracks vs DeltaY0 [SKIP]

NEvents Grouped by Track Count

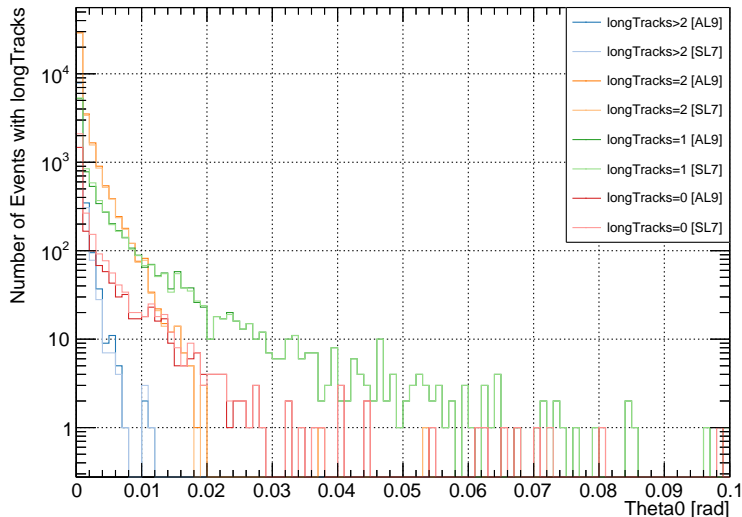

Events grouped by longTracks vs DeltaX0 [SKIP]

NEvents Grouped by Track Count

Events grouped by longTracks vs Theta0

NEvents Grouped by Track Count

Events grouped by longTracks vs DeltaRP

NEvents Grouped by Track Count

Comments on longTrack grouped Plots

- Good agreement between ALMA9 and CENTOS7
- Events with > 2 longTrack fall most rapidly [nothing past 10 mm]
- $= 2$ longTracks decay less rapidly [nothing past 30 mm]
- $= 1$ longTracks is relatively flat
- $= 0$ same as above - Not sure how to interpret
- In the plots where longTracks ≤ 1 AL9 performs bad at low separation
- Maybe logscale in x?

Definition of Efficiency Metrics

In General

- One Track Event \implies NOT reconstructed
- Two Track event + Opposite charges \implies reconstructed
- More than two track \implies complicated

Some Possible Eff. Metrics

- Number of Events with ≥ 2 longTracks [good proxy]
- (Can add charge identification to above but not necessary)
- MC Based Effi. [matching reconstructed to truth level data]

Definition of Fiducial

Before we define the efficiency we need to account for the detector acceptance by requiring the particle to be Fiducial.

Based on reconstructed data [Adapted from Sinead]

- Requires $longTracks == 2$
- $Track_r_atMaxRadius < 100$
- $t_st\{1, 2, 3\}_r < 100$

Based on truth level data

- $truthd0_r\{\{1, 2, 3\}\} < 100$
- $truthd1_r\{\{1, 2, 3\}\} < 100$
- Does not need the 2track cut while maintaining that particles of interest were Fiducial, While also being independent of ALMA9 or CENTOS7

Note:

- Where are NaNs coming from at the truth-level?

How do Fiducial Cuts perform?

Selection Step	Pass	All	Effi. (%)	Cum. Effi. (%)
2LongTracks	37807	60000	63.01	63.01
Opposite Charge	32427	37807	85.77	54.04
MaxRadius < 100	31489	32427	97.11	52.48
$t_st1_r < 100$	31471	31489	99.94	52.45
$t_st2_r < 100$	31458	31471	99.96	52.43
$t_st3_r < 100$	31383	31458	99.76	52.31

Table: Efficiencies and cumulative efficiencies at various selection steps. [ALMA9]

Selection Step	Pass	All	Effi. (%)	Cum. Effi. (%)
2LongTracks	36746	60000	61.24	61.24
Opposite Charge	30375	36746	82.66	50.62
MaxRadius < 100	29520	30375	97.19	49.20
$t_st1_r < 100$	29498	29520	99.93	49.16
$t_st2_r < 100$	29491	29498	99.98	49.15
$t_st3_r < 100$	29415	29491	99.74	49.03

Table: Efficiencies and cumulative efficiencies at various selection steps.[CENTOS7]

- ALMA9 performs better over most of the cuts.
- Using this fiducial cuts throws out 50% of the data.

Selection Step	Pass	All	Effi. (%)	Cum. Effi. (%)
$\text{truthd}\{0,1\}_{\text{st1_r}} < 100$	59634	60000	99.39	99.39
$\text{truthd}\{0,1\}_{\text{st2_r}} < 100$	58429	59634	97.98	97.38
$\text{truthd}\{0,1\}_{\text{st3_r}} < 100$	56703	58429	97.05	94.50

Table: Efficiencies and cumulative efficiencies for truth-level selection steps. [same for ALMA9/CENTOS7]

$\text{truthd_st1_r} =$

$$\begin{aligned} & \sqrt{\text{pow}(\text{truthd0_x}[1],2) + \text{pow}(\text{truthd0_y}[1],2)} > 100 \ \&\& \\ & \sqrt{\text{pow}(\text{truthd1_x}[1],2) + \text{pow}(\text{truthd1_y}[1],2)} \end{aligned}$$

Efficiency Definition

- Remove acceptance based on fiducial cuts at truth level
- Define Efficiency as the fraction of events with more than 2 reconstructed longTracks divided by the total number of events.

$$\text{Efficiency} = \frac{\text{NEvents}(\geq 2\text{longTracks})}{\text{NEvents}(\text{Total})}$$

≥ 2 Track Efficiency as a function of DeltaR0

≥ 2 Track Efficiency as a function of DeltaX0 [SKIP]

≥ 2 Track Efficiency as a function of DeltaY0 [SKIP]

≥ 2 Track Efficiency as a function of Θ_0

≥ 2 Track Efficiency as a function of DeltaRP

Comments on >2 Track Efficiency

- Good agreement between ALMA9 and CENTOS7
- Minor bump at very low separation (≈ 2 -6 mm) for ALMA9
- Error Bars too significant to say anything about large separation

Alternate Efficiency Definition

- Remove acceptance based on fiducial cuts at truth level
- Define Efficiency as the fraction of events with exactly 2 reconstructed longTracks divided by the total number of events.

$$\text{Efficiency} = \frac{\text{NEvents}(= 2\text{longTracks})}{\text{NEvents}(\text{Total})}$$

2 Track Efficiency as a function of DeltaR0

2 Track Efficiency as a function of DeltaX0 [SKIP]

2 Track Efficiency as a function of DeltaY0 [SKIP]

2 Track Efficiency as a function of Theta0

2 Track Efficiency as a function of DeltaRP

A More Robust Efficiency Metric [MC Based]

- Our interest is only in the primary two tracks from e^+e^-
- For acceptance: Truth Position of $e^+e^- < 100$
- **Identify the two primary tracks**
 - Wanted to use `t_pdg_parent` ...
 - Find closest to truth (by position and momenta)...
 - not trivial what is the margin of allowed error?
 - Highest momenta tracks?
 - Best approach is to use `t_truthHitRatio` + PID
- Can further quantify the “goodness” of the reconstructed primary tracks

Distribution of t_pdg_parent

t_pdg_parent	AL9	SL7
-11	2	0
0	2	0
22	2610	2397
32	115877	112809

Table: Count of t_pdg_parent

All particles are daughters of the Dark Photon?

Comments on Data in NTuples [SKIP]

- Need to add newly introduced variables to twiki.
- `t_st0_x`, `y`, `z` are filled with NaNs, We donot use/store `station0` vals?
- `t_pdg_parent` ???
- `truthParticleMatchedTracks` - What exactly is this column.?
